

## *Practical 2*

### *Jumping Rivers*

#### *Practical 1*

Advanced R programming: Practical 2

#### *Rprofile and Renviron*

1. Create an `.Rprofile` file. An easy way of creating the file is to use the R function `file.create`, so

```
file.exists("~/Rprofile")
```

Add the line

```
if (interactive()) {  
  message("Successfully loaded .Rprofile at ",  
    date(), "\n")  
}
```

to the file and restart R. Does the welcome message appear? 1. Try adding my suggestions to your `.Rprofile`, e.g.

```
options(prompt="R> ", digits=4,  
  show.signif.stars=FALSE)
```

and setting the CRAN mirror:

```
r = getOption("repos")  
r["CRAN"] = "http://cran.rstudio.com/"  
options(repos = r)  
rm(r)
```

1. Try adding a few functions to your `.Rprofile`. See chapter 2 in the notes for help. Use the hidden environment trick. Also take a look at this [stackoverflow question](http://stackoverflow.com/questions/14814812/r-profile-hidden-environment-trick)

<http://goo.gl/TLFLQR>

for ideas.

2. Create an `.Renviron` file and add the path to your packages.

#### *Argument matching*

R allows a variety of ways to match function arguments. For example, by position, by complete name, or by partial name. We didn't cover argument matching in the lecture, so let's try and figure out the rules from the examples below. First we'll create a little function to help

```
arg_explore = function(arg1, rg2, rg3)
  paste("a1, a2, a3 = ", arg1, rg2, rg3)
```

Next we'll create a few examples. Try and predict what's going to happen before calling the functions. One of these examples will raise an error - why?

```
arg_explore(1, 2, 3)
arg_explore(2, 3, arg1 = 1)
arg_explore(2, 3, a = 1)
arg_explore(1, 3, rg = 1)
```

Can you write down a set of rules that R uses when matching arguments?

Following on from the above example, can you predict what will happen with

```
plot(type = "l", 1:10, 11:20)
```

and

```
rnorm(mean = 4, 4, n = 5)
```

### *Functions as first class objects*

Suppose we have a function that performs a statistical analysis

```
## Use regression as an example
stat_ana = function(x, y) {
  lm(y ~ x)
}
```

However, we want to alter the input data set using different transformations. For example, the log transformation. In particular, we want the ability to pass arbitrary transformation functions to `stat_ana`.

- Add an argument `trans` to the `stat_ana()` function. This argument should have a default value of `NULL`.
- Use `is.function()` to test whether a function has been passed to `trans`, transform the vectors `x` and `y` when appropriate. For example,

```
stat_ana(x, y, trans = log)
```

would take log's of `x` and `y`.

- Allow the `trans` argument to take character arguments in addition to function arguments. For example, if we used `trans = 'normalise'`, then we would normalise the data i.e. subtract the mean and divide by the standard deviation.

*Variable scope*

Scoping can get tricky. **Before** running the example code below, predict what is going to happen

1. A simple one to get started

```
f = function(x) return(x + 1)
f(10)
```

1. A bit more tricky

```
f = function(x) {
  f = function(x) {
    x + 1
  }
  x = x + 1
  return(f(x))
}
f(10)
```

1. More complex

```
f = function(x) {
  f = function(x) {
    f = function(x) {
      x + 1
    }
    x = x + 1
    return(f(x))
  }
  x = x + 1
  return(f(x))
}
f(10)
```

```
## f3: = 10
```

```
## f2: = 11
```

```
## f1: = 12
```

- 1.

*Function closures*

Following the examples in the notes, where we created a function closure for the normal and uniform distributions. Create a similar closure for

- the Poisson distribution,<sup>1</sup>
- and the Geometric distribution.<sup>2</sup>

<sup>1</sup> Hint: see 'rpois' and 'dpois'.

<sup>2</sup> Hint: see 'rgeom' and 'dgeom'.

### *Mutable states*

In chapter 2, we created a random number generator where the `state`, was stored between function calls.

- Reproduce the `randu` generator from the notes and make sure that it works as advertised.
- When we initialise the random number generator, the very first state is called the `seed`. Store this variable and create a new function called `get_seed` that will return the initial seed, i.e.

```
r = randu(10)
r$r()
r$get_state()
r$get_seed()
```

- Create a variable that stores the number of times the generator has been called. You should be able to access this variable with the function `get_num_calls()`

```
r = randu(10)
r$get_num_calls()
r$r()
r$r()
r$get_num_calls()
```

### *Solutions*

Solutions are contained within the course package
